Canada Thistle

Fact Sheet No. 3.108 Natural Resources Series | Range

by K.G. Beck*

Canada thistle (Cirsium arvense) is an aggressive, creeping perennial weed that infests crops, pastures, rangeland, roadsides and noncrop areas. Generally, infestations start on disturbed ground, including ditch banks, overgrazed pastures, tilled fields or abandoned sites. Canada thistle reduces forage consumption in pastures and rangeland because cattle typically will not graze near infestations. In 2002, the Colorado Department of Agriculture surveyed counties and while incomplete, the results showed more than 100,000 acres infested with Canada thistle (Figure 1).

One plant can colonize an area 3 to 6 feet in diameter in one or two years. Canada thistle grows in a variety of soils and can tolerate up to 2 percent salt content. It is most competitive in deep, well-aerated, productive, cool soils. It usually occurs in 17- to 35-inch annual precipitation zones or where soil moisture is adequate. It is less common in light, dry soils. A survey conducted in 1998 showed Colorado has about 400,000 acres infested with Canada thistle.

Phenology

Emergence. Canada thistle develops from seed or vegetative buds in its root system. Horizontal roots may extend 15 feet or more and vertical roots may grow 6 to 15 feet deep. Canada thistle emerges from its root system in mid- to late spring (late April through May) and forms rosettes (Figure 2).

The greatest flush of root-derived plants occurs in spring, but another flush occurs in fall. A flush can occur anytime during the growing season when soil moisture is adequate. This is particularly a problem when Canada thistle growth is disturbed by tillage or herbicides. This feature can be manipulated to the land manager’s advantage.

Plants that germinate from seed do so at about the same time as root-derived shoots. Seedlings grow slowly and are sensitive to competition, particularly if shaded. Canada thistle seedlings develop a perennial habit (the ability to reproduce from their root systems) about seven to eight weeks after germination.

Reproduction and spread. Canada thistle begins to flower in late spring to early summer in response to 14- to 16-hour days (Figures 3, 4 and 5). Plants are male or female (dioecious) and grow in circular patches that often are one clone and sex. Female flowers produce a sweet odor and insects readily pollinate different sexed patches up to 200 feet apart.

Canada thistle develops seed sparingly. It may produce 1,000 to 1,500 seeds per flowering shoot. Generally, vegetative reproduction from its root system contributes to local spread and seed to long distance dispersal. Seed may be transported long distances by water, or attached to animals, clothing, farm equipment and other vehicles, and in contaminated crop seed. Also, wind may help disperse seed, but most often, the feathery pappus breaks off, leaving the seed attached to the parent plant to be dispersed by other means. Seed can remain viable in soil up to 22 years, and deep burial promotes survival longevity.

Quick Facts

- Canada thistle is a creeping perennial that reproduces from vegetative buds in its root system and from seed.
- It is difficult to control because its extensive root system allows it to recover from control attempts.
- Combining control methods is the best form of Canada thistle management.
- Persistence is imperative so the weed is continually stressed, forcing it to exhaust root nutrient stores and eventually die.

management. Maintain fertility and, if possible, moisture at optimum levels to favor grass or alfalfa growth. Soil analysis can easily determine fertility needs. Be cautious with nitrogen fertilizers, because excess available soil nitrogen may favor weed growth.

These are essential management steps to ensure optimum desirable plant growth and competition. However, competition alone seldom is effective against Canada thistle.

**Chemical control.** Read the label, follow directions and use precautions. Research at Colorado State University shows that Tordon 22K (picloram), Milestone (aminopyralid), Transline (clopyralid), Perspective (aminocyclopyrachlor + chlorsulfuron), Banvel/ Vanquish/Clarity (dicamba), and Telar (chlorsulfuron) are effective against Canada thistle in pastures, rangeland, natural areas, and noncrop settings. Canada thistle is difficult to control and re-treatment for one to three or more years after the initial application is common. Refer to Table 1 for use rates and application timing and always read the herbicide label before using the product. These herbicides are most effective when combined with cultural and/or mechanical control.

Colorado State University data also indicates that Banvel/Vanquish/Clarity or Telar are effective when combined with 2,4-D as a split-season application. Apply 2,4-D, 2 quarts per acre (A), in spring when Canada thistle is 10 to 15 inches tall, in pre-bud to early bud growth stages. Re-treat in fall with Banvel/ Vanquish/Clarity (2 quarts/A) or Telar (1 ounce/A) to re-growth. Use a surfactant (0.25 percent to 0.5 percent v/v; equivalent to 1 to 2 quarts of surfactant per 100 gallons of spray solution) with Telar for adequate control. Perspective should be applied in spring from the rosette to flower bud growth stages or in fall. CSU research shows that aminocyclopyrachlor (one of the Perspective components) and aminopyralid (Milestone) are absorbed primarily by the root system.

Curtail is clopyralid plus 2,4-D and is effective on Canada thistle but control tends to be less than from Transline. Research at Colorado State University shows that the performance of Curtail to control Canada thistle can be improved when preceded by two or three mowings. When Canada thistle infestations occur in situations where root growth would be restricted, such as habitats with high water tables, begin mowing when it is 12 to 15

**Management**

The key principle to Canada thistle control is to stress the plant and force it to use stored root nutrients. Canada thistle can recover from almost any stress, including control attempts, because of root nutrient stores. Therefore, returning infested land to a productive state occurs only over time. Success requires a sound management plan implemented over several years.

**Cultural control.** Grasses and alfalfa can compete effectively with Canada thistle if their growth is favored by good

inches tall. Repeat mowings at about one
month intervals. Apply Curtail at 2 to 3
quarts/A in October or about one month
after the third mowing. Follow this regimen
for two consecutive years.

**Mechanical control.** Mowing hay
meadows can be an effective tool if
combined with herbicide treatments.
Mowing alone is not effective unless
conducted at one-month intervals over
several growing seasons. Always combine
mowing with cultural and chemical control.
Mowing at hay cutting stimulates new
Canada thistle shoots to develop from its
root system.

In irrigated grass hay meadows, fall
herbicide treatments that follow mowing
can be an effective management system
because more Canada thistle foliage is
present after cutting to intercept herbicide.
Additionally, root nutrient stores decrease
after mowing because the plant draws on
them to develop new shoots.

If a Canada thistle infestation exists
in a field that will be rotated to alfalfa,
control the weed before seeding alfalfa.
Alfalfa is an effective competitor only
after it is established. It will not adequately
establish in a well-developed Canada thistle
infestation. A Canada thistle management
system can start with crop or grass
competition combined with herbicides,
with the field rotated to alfalfa when the
management plan ends.

**Biological control.** *Ceutorhynx litura*
is a weevil currently used as a biocontrol
agent in Colorado. The female lays eggs on
the underneath side of Canada thistle leaves
in early spring. Larvae bore into the main
leaf vein, then down into the plant’s crown
area. If the population is high enough, plant
death can occur, otherwise Canada thistle is
stressed and less vigorous.

*Ceutorhyncus* alone will not effectively
control Canada thistle. It must be combined
with other methods to be successful.
Combine the weevil with cultural
techniques that allow for maximum
desirable plant competition. Research to
combine *Ceutorhynx* with herbicides or
mowing has not been conducted. Research
has shown that biological and chemical
controls are compatible for musk thistle.
This is most likely true for Canada thistle as
well. *Ceutorhynx litura* is available from
the Colorado Department of Agriculture.

*Urophora cardui* is another biocontrol
insect available from the Colorado
Department of Agriculture. Females lay
eggs on apical meristems of developing
shoots. Larvae burrow into shoots. Their
feeding triggers huge galls to form that
stress the plant, sometimes killing it. Galls
that form near the terminal meristems (e.g.,
where flowers develop) keep the weed from
flowering and reduce seed set.
