Wolves and Livestock

Information Sheet 8.010 People and Predator Series | Colorado Wolves

By the Center for Human-Carnivore Coexistence (5/20)

What are the potential impacts of wolves on livestock in Colorado?

Impacts to livestock from wolves creates costs borne by livestock producers (see Wolf Economics Information Sheet). Calculating these costs, including mortality from wolf predation and other indirect impacts, is challenging. Part of the problem is not knowing exactly how many livestock are killed by wolves each year. For example, in the Northern Rocky Mountain states of Montana, Idaho, and Wyoming, the U.S. Fish and Wildlife Service (USFWS) confirmed a total of 136 cattle (both adults and calves) and 114 sheep (adults and lambs) killed by wolves in 2014. In contrast, the National Agricultural Statistics Service (NASS) reported 2,835 cattle and 453 sheep killed by wolves in the same region and year. The USFWS data are underestimates because they don’t include livestock that are killed by wolves but are never found or reported. The NASS numbers are based on a self-reported survey of livestock producers and do not include verification of kills. This leaves the accuracy of the NASS data in question, and the reports likely overestimate the number of livestock killed by wolves.

One way to estimate impact of wolves on the livestock industry is to calculate the proportion of livestock killed by wolves out of the total number of livestock in counties with wolves. Using USFWS data of confirmed wolf kills and NASS data of number of cattle, the calculated percentage of cattle killed by wolves in the Northern Rocky Mountain states is under 1%. However, this calculation ignores livestock that are not vulnerable to predation (e.g., in feedlots or on range where wolves do not occur) and thus likely underestimates the percentage. Nonetheless, the available data suggest that mortality caused by wolves is a small economic cost to the livestock industry as a whole.

However, in addition to mortalities, producers can also suffer indirect losses such as stress, sickness, and reduced weight gain and pregnancy rates when wolves scare, chase, or attack livestock. The indirect effect of wolves on livestock is not well studied so estimating the extent of indirect losses is difficult. Costs could be considerably higher when including unseen deaths, indirect losses, and expenses for producers to deter wolves or to seek compensation (see Wolf Economics Information Sheet). Indirect losses might be more likely on ranches where wolves are already killing cattle.

Although wolf depredation on cattle and sheep accounts for less than 1% of the economic cost to the livestock industry as a whole, the impacts to individual producers can be substantial.

- On rare occasions wolves only eat a portion of what is killed. Such events can have negative economic impacts and reinforce negative perceptions towards wolves. They are therefore important to minimize and prevent.
- Wildlife managers and livestock producers have a variety of management tools to reduce conflict with wolves. This entails alterations in livestock practices and/or efforts to manage wolves. Both non-lethal and lethal tools can be effective and used proactively to prevent conflict or reactively after conflict has occurred.

extension.colostate.edu
annual gross income from industry-wide livestock operations in the Northern Rocky Mountains, these costs are unevenly distributed and localized, with some producers suffering greater losses than others. For those impacted by wolf predation, the economic and emotional impacts can be substantial. Both direct and indirect losses could significantly affect the livelihood of individual ranchers operating on thin profit margins in volatile markets. At a stakeholder workshop in February 2020, ranchers shared their belief that wolf reintroduction poses a threat to rancher’s security regarding their livelihood and way of life.

Understanding why some producers are more vulnerable to wolf predation and others are not is an active area of research. The answer likely includes where livestock are grazed (some areas have more wolf activity than others); the type of livestock (sheep are more vulnerable than cattle); the type of operation (e.g., cow/calf versus stocker); range versus pasture operations; and how much the livestock are protected.

**Do wolves sometimes kill more prey than they can eat?**

On rare occasions predators kill many animals in excess of their food needs and only eat a portion of what is killed. This is sometimes called surplus killing, excess killing, or partial prey consumption. This behavior has been documented in a wide variety of predators, including wolves, foxes, weasels, bears, shrews, spiders, and insects. One of the better-known examples of partial prey consumption involves grizzly bears catching salmon, only eating the eggs and other select body parts, and discarding most of the remaining fish. Bears do this when there are so many fish that are easy to catch they can consume only the most nutritious and calorie rich parts of each caught fish.

For wolves, this type of predation event can occur on native ungulates such as deer, moose, or caribou and livestock such as sheep. It is generally believed that the vulnerability of the prey plays a large role in excess killing. For example, a study in Minnesota found that after an unusually severe winter, white-tailed deer were in very weak condition and for a few weeks wolves killed deer at much higher rates than normal and only partially consumed the carcasses. Like the bear example, wolves were likely trying to maximize their energetic gain and taking advantage of a short period when their prey was vulnerable.

Surplus killing on livestock may be more frequent than on wild prey because livestock are typically more vulnerable to predation. One study found that in the Northern Rocky Mountains from 1987-2003, wolves excessively killed sheep but not cattle. On average there were about 3 surplus killing events on sheep per year and an average of 8.85 sheep killed per attack. Compared to cattle, sheep and goats are thought to be more vulnerable because of their smaller size, fewer defenses (e.g., horns), and their tendency to occur in flocks that can supply large numbers of concentrated prey. Another factor is that corrals and other enclosures for livestock can make it easier to catch multiple livestock.

Although uncommon, such events can have negative economic impacts for producers. Such events can also be viewed as needless killing, reinforcing negative perceptions towards wolves. They are therefore important to minimize and prevent using approaches described below.

**What management tools are available to reduce livestock conflict with wolves?**

Wildlife managers use a variety of strategies to prevent or reduce livestock conflict with wolves. Some tools are reactive, meaning management occurs after the conflict happened. Other tools are proactive, meaning management occurs prior to conflict. Management actions are often situation-dependent and involve an integrated approach, combining both lethal and non-lethal methods.
Lethal methods can include regulated hunting (proactive) or targeted removal (reactive). Regulated hunting of wolves can limit wolf populations\(^{22-25}\). Lethal removal of wolves in reaction to conflict, for example killing livestock, can be effective if targeted to the correct individuals.\(^{26-28}\) Some studies have suggested that lethal removal of wolves only temporarily reduces depredation and actually may eventually increase conflicts.\(^{29-31}\) For example, one study concluded that killing wolves may displace depredations to neighboring properties.\(^{31}\) Another study reported that lethal removal might increase depredations the following year as new wolves breed and fill vacancies\(^{29}\), although these conclusions were contradicted when other researchers re-analyzed these data.\(^{32}\)

Proactive non-lethal tools can help prevent conflict. Such tools often focus on modifying wolf, livestock, and/or human behavior to minimize encounters.\(^{26,33-35}\) For example, physical or psychological barriers or scare tactics can be established to try to ward off wolves and other predators. These include fencing, fladry (flagging), lights, and sound devices, which rely on novelty and are effective at least temporarily.\(^{36}\) Livestock guardian dogs also can deter wolves, although wolves also can kill guard dogs and thus finding the right breed and number of guard dogs is important.\(^{37}\) Wolves also tend to avoid humans, so people accompanying livestock (e.g., herders, range riders, or scouts) can reduce encounters and also help manage herds proactively.\(^{38}\) Modifying livestock management practices can help, particularly during calving or lambing when animals are most vulnerable. For example, grazing strategies can be altered to avoid wolves, for instance by moving livestock away from known wolf dens. Removal of carcasses of livestock that have died can also be useful, as carcasses attract wolves and other predators. Such non-lethal tools entail costs in terms of time, labor, and money that need to be considered if they are to be implemented.

For all of these strategies the scale and the context will determine whether or not they are effective. For example, fladry is only appropriate for small pastures, guard dogs are only effective if they are large enough or in a big enough group to deter wolves, and livestock that are spread widely across a landscape are more difficult to protect.

Local communities can apply combinations of strategies and tools. For example, the ranching community in the Blackfoot Valley of Montana uses a collaborative, grass-roots approach to reduce conflicts with predators through proactive strategies.\(^{39}\) They remove and compost livestock carcasses, fence calving areas, and employ wildlife technicians to monitor livestock and wolves. This has helped reduce both the number of livestock and wolves killed in the community. The program is funded from a combination of sources, including governmental agencies, private foundations, corporations, and individual donations.\(^{40}\)

In addition, producers can be financially compensated for livestock lost to wolves (see Wolf Economics Information Sheet).\(^{7-9,41,42}\) Such programs are often underutilized by producers. These compensation programs have also been criticized for their high costs and burden of proof to verify kills, inadequate funding.
to fully compensate for losses, and lack of incentives to prevent conflict. Alternative incentive models, where producers are paid to coexist with wildlife, including carnivores, are being proposed as we learn from ongoing programs. These models are commonly referred as “payment for ecosystem services”.

Several useful manuals exist to help landowners with approaches to reduce conflict between livestock and wolves. These documents review in more detail the variety of tools and best management practices available to reduce and even prevent livestock losses to predators.
